

The entry wound on the Governor's back is described as of "small size"

(R92). The size is not given. It was known. The Commission's theory was that a single bullet exited the President's neck and entered the Governor's back, thereafter causing all his injuries. The size of the alleged point of entry in the President's neck, according to the Dallas doctors was about a fifth of an inch in diameter. ~~But~~ generally but not always, entry wounds are smaller than exit wounds. Doctor (4H) said the governor's back wound measured 2 centimeters, or about five-eighth of an inch. This is almost three times the diameter and damaged an even larger area, indicating something happened to the bullet, such as the beginning of tumbling, between the time it entered and left the President, if that is what it did, and the time it hit the Governor.

Corrected #679 (#13) indicating not front

Asked if the representation of the wrist wound was accurate, Dr. Gregory

replied, "They do not in that, though the locations of wounds on the forearm is correct, and the dimensions, it is my opinion that entrance and exit terms have been reversed" (4H 126)
